# Metastability and transition events

Consider the diffusion process defined by

$$d\boldsymbol{X}_t^{\varepsilon} = -\nabla U(\boldsymbol{X}_t^{\varepsilon})dt + \sqrt{\varepsilon}d\boldsymbol{W}_t$$

where  $W_t$  is the standard multi-dimensional Wiener process, U(x) is assumed to be a smooth Morse function, i.e. the critical points of U are non-degenerate in the sense that the Hessian matrices at the critical points are non-degenerate.

The above picture can be best illustrated in the following one dimensional example (see Figure below) with the double-well potential

$$U(x) = \frac{1}{4}(x^2 - 1)^2.$$

► The potential U has two local minima at x<sub>+</sub> = 1 and x<sub>-</sub> = -1, and one saddle at x<sub>s</sub> = 0. x<sub>s</sub> is also called the transition state between x<sub>+</sub> and x<sub>-</sub>. Thus we have two basins of attraction

$$B_{-} = \{x \mid x \le 0\} \text{ and } B_{+} = \{x \mid x \ge 0\}.$$

Most of time, X<sub>t</sub> wanders around x<sub>+</sub> or x<sub>−</sub>. But after exponentially large time scales in O(1/ε), X<sub>t</sub><sup>ε</sup> hops between the regions B<sub>+</sub> and B<sub>−</sub>, which manifests basic features of rare events.

(a) Potential function U(x)

(b) A typical trajectory of  $X_t$ 

Figure: Illustration of rare events in the 1D double-well potential. Left panel: The symmetric double-well potential with two metastable states at  $x_{+} = 1$  and  $x_{-} = -1$ . Right panel: A specific trajectory of  $X_{t}$ , which wanders around  $x_{+}$  or  $x_{-}$  and hops after a sufficiently long time.

# Metastability: key questions

In physical terms, the local minima or the basin of attractions are called metastable states. Obviously, when we discuss metastability, the key issue is that of the time scale. In rare event studies, one is typically concerned about the following three key questions:

1. What is the most probable transition path and how to compute it? When the dimension of  $X_t^{\varepsilon}$  is bigger than 1, this becomes a meaningful question.

### Metastability: key questions

In physical terms, the local minima or the basin of attractions are called metastable states. Obviously, when we discuss metastability, the key issue is that of the time scale. In rare event studies, one is typically concerned about the following three key questions:

- 1. What is the most probable transition path and how to compute it? When the dimension of  $X_t^{\varepsilon}$  is bigger than 1, this becomes a meaningful question.
- 2. Where is the transition state, i.e. the neighboring saddle point, for a transition event starting from a metastable state? Presumably the saddle points can be identified from the eigenvalue analysis of the Hessian of U. However, when the dimension is high and the landscape of U is complex, it is not trivial.

# Metastability: key questions

In physical terms, the local minima or the basin of attractions are called metastable states. Obviously, when we discuss metastability, the key issue is that of the time scale. In rare event studies, one is typically concerned about the following three key questions:

- 1. What is the most probable transition path and how to compute it? When the dimension of  $X_t^{\varepsilon}$  is bigger than 1, this becomes a meaningful question.
- 2. Where is the transition state, i.e. the neighboring saddle point, for a transition event starting from a metastable state? Presumably the saddle points can be identified from the eigenvalue analysis of the Hessian of U. However, when the dimension is high and the landscape of U is complex, it is not trivial.
- 3. How large is the typical transition time from a metastable state? Answer of this question helps understanding the stability of a metastable state, which corresponds to the key time scale issue.

#### Rare events: setup

We will present some recent methodologies in the literature to answer these questions.

#### Rare events: setup

- We will present some recent methodologies in the literature to answer these questions.
- Consider the SDEs

$$d\boldsymbol{X}_t^arepsilon = \boldsymbol{b}(\boldsymbol{X}_t^arepsilon) dt + \sqrt{arepsilon} \boldsymbol{\sigma}(\boldsymbol{X}_t^arepsilon) \cdot d\boldsymbol{W}_t, \qquad \boldsymbol{X}_0^arepsilon = \boldsymbol{y} \in \mathbb{R}^d.$$

We assume that the standard Lipschitz and uniform ellipticity conditions on  $\boldsymbol{b}$  and  $\boldsymbol{\sigma}$  hold and denote the transition pdf by  $p_{\varepsilon}(\boldsymbol{x},t|\boldsymbol{y})$ . We are interested in the behavior of its solution for small  $\varepsilon$ .

Further detailed analysis on the behavior of the pdf is studied below.

# WKB analysis

 Inspired by the form of probability distribution function of Brownian dynamics, we insert the Wentzel-Kramers-Brillouin (WKB) ansatz

$$p_{\varepsilon}(\boldsymbol{x},t|\boldsymbol{y}) \sim \exp\left(-\varepsilon^{-1}\phi(\boldsymbol{x},t|\boldsymbol{y})\right)$$

into the forward Kolmogorov equation associated with the SDEs

$$\frac{\partial p_{\varepsilon}}{\partial t} = -\nabla \cdot (\boldsymbol{b}(\boldsymbol{x})p_{\varepsilon}) + \frac{\varepsilon}{2}\nabla^2 : (\boldsymbol{A}(\boldsymbol{x})p_{\varepsilon}).$$

where  $\boldsymbol{A}(\boldsymbol{x}) = \boldsymbol{\sigma} \boldsymbol{\sigma}^T(\boldsymbol{x}) = (a_{ij}(\boldsymbol{x}))$  is the diffusion matrix.

# WKB analysis

 Inspired by the form of probability distribution function of Brownian dynamics, we insert the Wentzel-Kramers-Brillouin (WKB) ansatz

$$p_{\varepsilon}(\boldsymbol{x},t|\boldsymbol{y}) \sim \exp\left(-\varepsilon^{-1}\phi(\boldsymbol{x},t|\boldsymbol{y})\right)$$

into the forward Kolmogorov equation associated with the SDEs

$$rac{\partial p_{arepsilon}}{\partial t} = -
abla \cdot (oldsymbol{b}(oldsymbol{x})p_{arepsilon}) + rac{arepsilon}{2}
abla^2 : (oldsymbol{A}(oldsymbol{x})p_{arepsilon}).$$

where  $A(x) = \sigma \sigma^T(x) = (a_{ij}(x))$  is the diffusion matrix.

 Collecting the leading order terms gives a time-dependent Hamilton-Jacobi equation

$$\frac{\partial \phi}{\partial t} = H(\boldsymbol{x}, \nabla_{\boldsymbol{x}} \phi),$$

where H is the Hamiltonian with the form

$$H(\boldsymbol{x},\boldsymbol{p}) = \boldsymbol{b}^{T}(\boldsymbol{x})\boldsymbol{p} + \frac{1}{2}\boldsymbol{p}^{T}\boldsymbol{A}(\boldsymbol{x})\boldsymbol{p} = \sum_{i} b_{i}p_{i} + \frac{1}{2}\sum_{ij} a_{ij}p_{i}p_{j}.$$

### Hamilton-Jacobi Theory

We will call p the momentum variable for its formal correspondence in classical mechanics. The solution of this equation can be characterized by the variational principle:

$$\begin{split} \phi(\pmb{x},t|\pmb{y}) &= \inf_{\varphi} \big\{ I_t[\pmb{\varphi}]: \quad \pmb{\varphi} \text{ is absolutely continuous in } [0,t] \\ & \text{ and } \pmb{\varphi}(0) = \pmb{y}, \pmb{\varphi}(t) = \pmb{x} \big\}, \end{split}$$

where  $I_t$  is the action functional

$$I_t[oldsymbol{arphi}] = \int_0^t L(oldsymbol{arphi}, \dot{oldsymbol{arphi}}) ds$$

and L is called the Lagrangian

$$L(x, z) = \frac{1}{2} \|z - b(x)\|_{A}^{2}$$

where the norm  $\|\boldsymbol{z}\|_{\boldsymbol{A}}^2 := \boldsymbol{z}^T \boldsymbol{A}^{-1} \boldsymbol{z}.$ 

## Lagrangian and Hamiltonian

The Lagrangian L is the dual of the Hamiltonian H in the sense of Legendre-Fenchel transform

$$L(\boldsymbol{x}, \boldsymbol{z}) = \sup_{\boldsymbol{p}} \{ \boldsymbol{p} \cdot \boldsymbol{z} - H(\boldsymbol{x}, \boldsymbol{p}) \}.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

### Lagrangian and Hamiltonian

**Computing Transition Paths** 

Transition Rates

Implications of WKB results

 The WKB analysis has given us the intuition that the probability

$$\mathbb{P}(\boldsymbol{X}_t^{\varepsilon} \in B) symp \exp(-arepsilon^{-1}C) \quad \text{ as } arepsilon o 0,$$

where B is an open set, and the symbol  $\asymp$  means exponential equivalence, i.e. we have  $\lim_{\varepsilon \to 0} \varepsilon \ln A_{\varepsilon}/B_{\varepsilon} = 1$  if  $A_{\varepsilon} \asymp B_{\varepsilon}$ . The constant C will be positive if  $x(t) \notin B$ , and 0 otherwise.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

### Implications of WKB results

 The WKB analysis has given us the intuition that the probability

$$\mathbb{P}(\boldsymbol{X}^{\varepsilon}_t \in B) \asymp \exp(-\varepsilon^{-1}C) \quad \text{ as } \varepsilon \to 0,$$

where B is an open set, and the symbol  $\asymp$  means exponential equivalence, i.e. we have  $\lim_{\varepsilon \to 0} \varepsilon \ln A_{\varepsilon}/B_{\varepsilon} = 1$  if  $A_{\varepsilon} \asymp B_{\varepsilon}$ . The constant C will be positive if  $x(t) \notin B$ , and 0 otherwise.

This large deviation type estimate is even true in path space C[0,T].

### Large deviations on path space

First let us quote the large deviation result for the SDEs.

#### Theorem

Under the condition that  $\mathbf{b}(\mathbf{x})$  and  $\boldsymbol{\sigma}(\mathbf{x})$  is bounded and Lipschitz, and  $\mathbf{A}(\mathbf{x})$  is uniformly elliptic, we have that for any T > 0, the following large deviation estimates for  $\mathbf{X}^{\varepsilon}$ .

(i) Upper bound. For any closed set  $F \subset (C[0,T])^d$ ,

$$\limsup_{\varepsilon \to 0} \varepsilon \ln \mathbb{P}(\boldsymbol{X}^{\epsilon} \in F) \leq -\inf_{\boldsymbol{\varphi} \in F} I_T[\boldsymbol{\varphi}].$$

(ii) Lower bound. For any open set  $G \subset (C[0,T])^d$ ,

$$\liminf_{\varepsilon \to 0} \varepsilon \ln \mathbb{P}(\boldsymbol{X}^{\epsilon} \in G) \ge -\inf_{\boldsymbol{\varphi} \in G} I_T[\boldsymbol{\varphi}].$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

### Large deviations on path space

First let us quote the large deviation result for the SDEs.

#### Theorem

Under the condition that  $\mathbf{b}(\mathbf{x})$  and  $\boldsymbol{\sigma}(\mathbf{x})$  is bounded and Lipschitz, and  $\mathbf{A}(\mathbf{x})$  is uniformly elliptic, we have that for any T > 0, the following large deviation estimates for  $\mathbf{X}^{\varepsilon}$ .

(i) Upper bound. For any closed set  $F \subset (C[0,T])^d$ ,

$$\limsup_{\varepsilon \to 0} \varepsilon \ln \mathbb{P}(\boldsymbol{X}^{\epsilon} \in F) \leq -\inf_{\boldsymbol{\varphi} \in F} I_T[\boldsymbol{\varphi}].$$

(ii) Lower bound. For any open set  $G \subset (C[0,T])^d$ ,

$$\liminf_{\varepsilon \to 0} \varepsilon \ln \mathbb{P}(\boldsymbol{X}^{\epsilon} \in G) \geq -\inf_{\boldsymbol{\varphi} \in G} I_T[\boldsymbol{\varphi}].$$

Here  $I_T[\varphi]$  is the rate functional defined in WKB analysis if  $\varphi$  is absolutely continuous with square integrable  $\dot{\varphi}$  and satisfies  $\varphi(0) = \boldsymbol{y}$ , otherwise  $I_T[\varphi] = \infty$ .

### Large deviations for 1D Brownian motion

The proof of this theorem is beyond the scope of this course. However we will give a formal derivation by path integral approach.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ
## Large deviations for 1D Brownian motion

The proof of this theorem is beyond the scope of this course. However we will give a formal derivation by path integral approach.

It is straightforward that the one-dimensional SDE

$$dX_t^{\varepsilon} = \sqrt{\varepsilon} dW_t, \qquad X_0 = 0$$

has solution  $X_t^{\varepsilon} = \sqrt{\varepsilon} W_t$ .

#### Large deviations for 1D Brownian motion

- The proof of this theorem is beyond the scope of this course. However we will give a formal derivation by path integral approach.
- It is straightforward that the one-dimensional SDE

$$dX_t^{\varepsilon} = \sqrt{\varepsilon} dW_t, \qquad X_0 = 0$$

has solution  $X_t^{\varepsilon} = \sqrt{\varepsilon} W_t$ .

• Using the path integral representation, the probability distribution induced by  $\{X_t^{\varepsilon}\}$  on C[0,T] can be formally written as

$$dP^{\varepsilon}[\varphi] = Z^{-1} \exp\left(-\frac{1}{2\varepsilon} \int_0^T |\dot{\varphi}(s)|^2 ds\right) D\varphi$$
$$= Z^{-1} \exp\left(-\frac{1}{\varepsilon} I_T[\varphi]\right) D\varphi$$

Note that  $I_T[\varphi]$  can be  $+\infty$  if  $\varphi$  is not absolutely continuous and square integrable or does not satisfy the corresponding initial condition.

#### Large deviations for SDEs

Then let us consider the stochastic ODE

$$dX_t^{\varepsilon} = b(X_t^{\varepsilon})dt + \sqrt{\varepsilon}\sigma(X_t^{\varepsilon})dW_t, \qquad X_0 = y.$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

We are interested in the asymptotic behavior of the probability distribution  $P^{\varepsilon}$  induced by  $\{X_t^{\varepsilon}\}$ .

#### Large deviations for SDEs

Then let us consider the stochastic ODE

$$dX_t^{\varepsilon} = b(X_t^{\varepsilon})dt + \sqrt{\varepsilon}\sigma(X_t^{\varepsilon})dW_t, \qquad X_0 = y.$$

We are interested in the asymptotic behavior of the probability distribution  $P^{\varepsilon}$  induced by  $\{X_t^{\varepsilon}\}$ .

From the SDE we have  $\dot{W}_t = (\sqrt{\varepsilon})^{-1} \sigma^{-1} (X_t^{\varepsilon}) (\dot{X}_t^{\varepsilon} - b(X_t^{\varepsilon})).$ Hence

$$\int_0^T \dot{W}_t^2 dt = \varepsilon^{-1} \int_0^T |\sigma^{-1}(X_t^\varepsilon)(\dot{X}_t^\varepsilon - b(X_t^\varepsilon))|^2 dt.$$

From the distribution  $dP^{arepsilon}[arphi]$  induced by  $\sqrt{arepsilon}W_t$ , we obtain

$$dP^{\varepsilon}[\varphi] = Z^{-1} \exp\left(-\frac{1}{\varepsilon}I_T[\varphi]\right) D\varphi,$$

where  $I_T[\varphi]$  is finite if  $\varphi$  is absolutely continuous with square integrable  $\dot{\varphi}$  and satisfies  $\varphi(0) = y$ , and  $I_T[\varphi] = \infty$  otherwise.

200

## Rate functional

Based on the theorem above and Varadhan's lemma, we have the asymptotics

$$-\varepsilon \log P^{\varepsilon}(\mathcal{B}) \sim \inf_{\varphi \in \mathcal{B}} I_T[\varphi], \quad \varepsilon \to 0$$

for a reasonable set  $\mathcal{B}$  in C[0,T].

This motivates a natural characterization of the most probable transition paths in the limit ε → 0.

#### Rate functional

Based on the theorem above and Varadhan's lemma, we have the asymptotics

$$-\varepsilon \log P^{\varepsilon}(\mathcal{B}) \sim \inf_{\varphi \in \mathcal{B}} I_T[\varphi], \quad \varepsilon \to 0$$

for a reasonable set  $\mathcal{B}$  in C[0,T].

- This motivates a natural characterization of the most probable transition paths in the limit  $\varepsilon \to 0$ .
- ► Given a set of path B in C[0,T] we can define the optimal path in B as the path φ<sup>\*</sup> that has the maximum probability or minimal action

$$\inf_{\varphi \in \mathcal{B}} I_T(\varphi) = I_T(\varphi^*),$$

if this minimization problem has a solution.

## Rate functional

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

if this minimization problem has a solution.

Such a path is called a minimum (or least) action path.

#### Minimum action path

• The minimum action path has special features in case that  $\boldsymbol{b}(\boldsymbol{x}) = -\nabla U(\boldsymbol{x})$  and  $\boldsymbol{\sigma}(\boldsymbol{x}) = \boldsymbol{I}$ .

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

#### Minimum action path

- The minimum action path has special features in case that  $b(x) = -\nabla U(x)$  and  $\sigma(x) = I$ .
- Assume that A and B are two neighboring metastable states of U separated by the saddle point C. Define B = {φ : φ ∈ (C[0,T])<sup>d</sup>, φ(0) = A, φ(T) = B}. We are interested in the minimum action path φ ∈ B and let the transition time T to be free

$$\inf_{T>0} \inf_{\varphi(0)=A,\varphi(T)=B} I_T[\varphi].$$

We have the following characterizations.

# Minimum action/energy path

#### Lemma

The minimum action path  $\varphi$  of the Brownian dynamics is comprised of two parts defined through functions  $\varphi_1$  and  $\varphi_2$  as

$$\dot{\varphi}_1(s) = \nabla U(\varphi_1(s)), \quad \varphi_1(-\infty) = A, \varphi_1(\infty) = C,$$

$$\dot{\varphi}_2(s) = -\nabla U(\varphi_2(s)), \quad \varphi_2(-\infty) = C, \varphi_2(\infty) = B,$$

and the minimum action is achieved as

$$I^* = I_{\infty}(\varphi_1) + I_{\infty}(\varphi_2) = I_{\infty}(\varphi_1) = 2(U(C) - U(A)) = 2\Delta U_{AB}.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

## Minimum action path: Proof

#### Proof.

It is not difficult to convince oneself that the minimum in T is attained when  $T = \infty$  since A, B and C are all critical points (see Exercise 13.1). To see why the minimization problem in is solved by the path defined above, we first note that

$$I_{\infty}[\boldsymbol{\varphi}_1] = 2\Delta U_{AB}, \quad I_{\infty}[\boldsymbol{\varphi}_2] = 0.$$

In addition, for any path  $\varphi$  connecting A and a point  $\tilde{C}$  on the separatrix that separates the basins of attraction of A and B, we have

$$\begin{split} I_{\infty}[\boldsymbol{\varphi}] &= \frac{1}{2} \int_{\mathbb{R}} (\dot{\boldsymbol{\varphi}} - \nabla U, \dot{\boldsymbol{\varphi}} - \nabla U) dt + 2 \int_{\mathbb{R}} \dot{\boldsymbol{\varphi}} \cdot \nabla U dt \\ &\geq 2 \int_{\mathbb{R}} \dot{\boldsymbol{\varphi}} \cdot \nabla U dt = 2(U(\tilde{C}) - U(A)) \geq 2\Delta U_{AB} \end{split}$$

since C is the minimum of U on the separatrix. Combing the result above we obtain the minimum  $I^* = 2\Delta U_{AB}$  and  $I^* = 2\Delta U_{AB}$ 

Thus the most probable transition path is then the combination of φ<sub>1</sub> and φ<sub>2</sub>: φ<sub>1</sub> goes along the steepest ascent dynamics and therefore requires the action of the noise. φ<sub>2</sub> simply follows the steepest descent dynamics and therefore does not require the help from the noise.

- Thus the most probable transition path is then the combination of φ<sub>1</sub> and φ<sub>2</sub>: φ<sub>1</sub> goes along the steepest ascent dynamics and therefore requires the action of the noise. φ<sub>2</sub> simply follows the steepest descent dynamics and therefore does not require the help from the noise.
- Putting them together we obtain the characterization for the most probable transition path of Brownian dynamics

$$\dot{\boldsymbol{\varphi}}(s) = \pm \nabla U(\boldsymbol{\varphi}(s)).$$

Paths that satisfy this equation are called the *minimum* energy path (MEP).

- Thus the most probable transition path is then the combination of φ<sub>1</sub> and φ<sub>2</sub>: φ<sub>1</sub> goes along the steepest ascent dynamics and therefore requires the action of the noise. φ<sub>2</sub> simply follows the steepest descent dynamics and therefore does not require the help from the noise.
- Putting them together we obtain the characterization for the most probable transition path of Brownian dynamics

$$\dot{\boldsymbol{\varphi}}(s) = \pm \nabla U(\boldsymbol{\varphi}(s)).$$

Paths that satisfy this equation are called the *minimum* energy path (MEP).

One can write the equation above as:

$$\left(\nabla U(\boldsymbol{\varphi})\right)^{\perp} = 0,$$

where  $(\nabla U(\varphi))^{\perp}$  denotes the component of  $\nabla U(\varphi)$  normal to the curve described by  $\varphi$ .

Question: How to compute the MEP for complicate systems?

# Mean First Passage Time (MFPT)

From the boundary conditions for the backward equation, we have R(x,t)|<sub>x=b</sub> = 0 and ∂<sub>x</sub>R(x,t)|<sub>x=a</sub> = 0, which implies the boundary conditions for τ(x):

$$\partial_x \tau(x)|_{x=a} = 0, \quad \tau(x)|_{x=b} = 0.$$

So  $\tau(x)$  satisfies equation:

$$\mathcal{A}\tau(x) = -U'(x)\tau'(x) + \varepsilon\tau''(x) = -1 \text{ for } x \in (a,b).$$

With boundary conditions:

$$\tau|_{x=b} = 0, \ \tau'|_{x=a} = 0.$$

## Mean First Passage Time (MFPT)

From the boundary conditions for the backward equation, we have  $R(x,t)|_{x=b} = 0$  and  $\partial_x R(x,t)|_{x=a} = 0$ , which implies the boundary conditions for  $\tau(x)$ :

$$\partial_x \tau(x)|_{x=a} = 0, \quad \tau(x)|_{x=b} = 0.$$

So  $\tau(x)$  satisfies equation:

$$\mathcal{A} au(x) = -U'(x) au'(x) + arepsilon au''(x) = -1 \ \ ext{for} \ x \in (a,b).$$

With boundary conditions:

$$\tau|_{x=b} = 0, \ \tau'|_{x=a} = 0.$$

It has the solution

$$\tau(x) = \frac{1}{\epsilon} \int_{x}^{b} e^{\frac{U(y)}{\varepsilon}} \int_{a}^{y} e^{-\frac{U(z)}{\varepsilon}} dz dy.$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

#### MFPT in Zero-Temperature Limit

▶ Take  $a \to -\infty$ ,  $b \to x_B$  and  $x = x_A$ , thus obtain

$$\tau(x_A) = \frac{1}{\epsilon} \int_{x_A}^{x_B} \int_{-\infty}^{y} e^{\frac{U(y) - U(z)}{\epsilon}} dz dy.$$

#### MFPT in Zero-Temperature Limit

▶ Take  $a \to -\infty$ ,  $b \to x_B$  and  $x = x_A$ , thus obtain

$$\tau(x_A) = \frac{1}{\epsilon} \int_{x_A}^{x_B} \int_{-\infty}^{y} e^{\frac{U(y) - U(z)}{\varepsilon}} dz dy$$

• Define the function F(y, z) = U(y) - U(z) on the domain

$$S = \{(y,z) : y \in [x_A, x_B] \text{ and } z \in (-\infty, y] \text{ for any } y\}.$$

We have

$$\max_{(y,z)\in S} F(y,z) = \Delta U_{AB} = U(x_C) - U(x_A)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

at  $(y, z) = (x_C, x_A)$ .

## MFPT in Zero-Temperature Limit

▶ Take  $a \to -\infty$ ,  $b \to x_B$  and  $x = x_A$ , thus obtain

$$\tau(x_A) = \frac{1}{\epsilon} \int_{x_A}^{x_B} \int_{-\infty}^{y} e^{\frac{U(y) - U(z)}{\varepsilon}} dz dy$$

• Define the function F(y, z) = U(y) - U(z) on the domain

$$S = \{(y,z) : y \in [x_A, x_B] \text{ and } z \in (-\infty, y] \text{ for any } y\}.$$

We have

$$\max_{(y,z)\in S} F(y,z) = \Delta U_{AB} = U(x_C) - U(x_A)$$

at  $(y, z) = (x_C, x_A)$ .

With Laplace asymptotics in the 2D domain S, we have

$$\tau(x) \approx \tau(x_A) \sim \frac{2\pi}{\sqrt{|U''(x_C)|U''(x_A)}} e^{\frac{\Delta U_{AB}}{\varepsilon}}$$

for any  $x \leq x_C - \delta_0$ , where  $\delta_0$  is a positive constant. We implicitly require that  $U''(x_A)$  and  $|U''(x_C)|$  are positive.

# 1D Transition Rates

• The formula tells us that the transition time is exponentially large in  $O(\Delta U_{AB}/\varepsilon)$ .

# 1D Transition Rates

- The formula tells us that the transition time is exponentially large in  $O(\Delta U_{AB}/\varepsilon)$ .
- The derivations also tell that the length of transition times does not heavily depends on where the particle starts from.

## 1D Transition Rates

- The formula tells us that the transition time is exponentially large in  $O(\Delta U_{AB}/\varepsilon)$ .
- The derivations also tell that the length of transition times does not heavily depends on where the particle starts from.
- In the considered case, we naturally define the transition rate

$$k_{AB} = \frac{1}{\tau(x_A)} = \frac{\sqrt{|U''(x_C)|U''(x_A)}}{2\pi} \exp\left(-\frac{\Delta U_{AB}}{\varepsilon}\right).$$

This is the celebrated Kramers reaction rate formula in the Brownian dynamics case, which is also called Arrhenius's law of reaction rates.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

## Multi-dimensional Transition Rates

In the multi-dimensional case with index-one saddle point x<sub>C</sub>, one can also derive the reaction rate asymptotics

$$k_{AB} = \frac{\sqrt{|\lambda_s|}}{2\pi} \sqrt{\frac{\det H_A}{\det H_C^{\perp}}} \exp\left(-\frac{\Delta U_{AB}}{\varepsilon}\right)$$

for the Brownian dynamics, where  $\lambda_s < 0$  is the unique negative eigenvalue of the Hessian  $H_C = \nabla^2 U(\boldsymbol{x}_C)$ ,  $H_A = \nabla^2 U(\boldsymbol{x}_A)$ ,  $H_C^{\perp}$  is the restriction of  $H_C$  on the (d-1)-dimensional stable manifold at  $\boldsymbol{x}_C$ .
